

MED-R5 safeguard deviation protocol

disease: custom (paste genes)

experiment: primary target engagement check

focus: sirolimus (rapamycin)

goal: verify that the primary engages the main covered disease genes before broader spend

cheap readout: low-cost mechanistic marker panel

stop rule: stop if no signal appears in the primary-covered target set

bundle: sirolimus (rapamycin), curcumin

hypothesis anchor: sirolimus (rapamycin), curcumin could neutralize the signed disease deviation of custom (paste genes)

reasoning trace

- primary drug sirolimus (rapamycin) chosen first because it closes MTOR
- support fill picked curcumin because it newly closes BDNF with net gain 0.19
- early kill this first because the full stack should not continue if the lead drug misses core targets

safeguard deviation protocol

1. verify assay model and control before any full run.
2. run the cheapest target-engagement readout first.
3. cap spend until signal and spillover are both visible.
4. document every deviation, storage issue, timing drift, and readout failure.
5. stop immediately if stop-rule is hit and store the miss in safeguard memory.

mistakes avoided / estimated savings

potential savings from avoided mistakes: EUR 5,700

main avoided losses: wrong model continuation, false-positive bundle spend, uncaught spillover, and repetition of the same failed setup.
