

i have a pipeline that indirectly farms long term a patented compound and short term it makes the doctor have better success rate.

- it looks for a specific niche
- ie immunology
- then finds medicine there that's good
- then sees what this does in body (ie gene, receptor activator)
- then if x of those -> looks for 1 natural compound that fills 1 until x filled
- once x filled maybe ie 7 genes filled across 6 compounds (1 activates 2 genes)
- proposes early kill experiment that if medicine x and one pill or combo of those 6 compounds as addition to the medicine x
- better succes rate ?
- could lead to side effects too which is why early kill
- first safe experiment would be translating that to 6 compounds but these would be found in diet
- ie oncology medicine + diet containing these compounds
- if nasty side effects of treatment could look into which genes could counter act this in practice
- ie nausea -> cb1 receptor activated through hemp food
- and also the gene cross over tool im not sure how to use that but really
- if the medicinal patient maybe got oncology and has diabetes
- look for medicine in diabetes which activates certain genes
- so the right medication gets chosen
- ie can't have patient doing oncology medicine in addition to diabetes and maybe eat some food activating genes offsetting oncology med side effects

- or maybe if oncology medicine activates genes which also be active due to medicine for diabetes
- means maybe more side effects ie nausea
- means got to look for genes off setting ie nausea -> cb1
- and also hard ware connected to the early kill experiment ie building out sw which does like temp proposal if cell research
- converts temp to json
- program it into hw using constraints
- back up environment where cells move into fast if main env fails
- does so quickly cus area need to be small so can be used in aerospace
- and ui too
- some sw really hard to develop without a lab setting
